

Same configuration, three seeds: two lean short and one leans long — and the short ones earn their edge against that lean

cell 1 only (BSQ, OHLCV-only), 1,402,520 decisions per unit at the pinned $h = 15$. The lean propagates: decision activity spans $24 \times (0.0193\text{--}0.4702)$ and net IR at the pinned cost spans 118 points. In (c) the sample drifted UP (always-long IR $+0.3704$), so a short lean loses by construction. Seed 4 uses the benchmark of the names it traded; 0 and 2 the evaluated cross-section.
