

the five cells

capacity is controlled, not assumed

20.058 vs 20.000 bits per bar (0.058 apart)

31,795,200 vs 31,725,568 realized params (0.219% of the model apart; 10,493,952 of each are MTP heads)

what shuffling the block destroys — and what it leaves

mean |corr| micro ↔ OHLCV, contemporaneous

before 0.2037

after 0.0005

destroyed

mean |lag-1 autocorr|, micro

before 0.4165

after 0.0006

destroyed

mean |corr| micro ↔ micro, within-bar

before 0.2886

after 0.2886

preserved

mean |corr| OHLCV ↔ OHLCV, within-bar

before 0.3105

after 0.3105

preserved

the handicap this creates, disclosed not removed

cell 4's micro dims are partly free: they share structure the code already carries. Shuffling removes that sharing too, so $\Delta\text{IR}(4-5)$ is (information) + (capacity handicap), not information alone. The handicap is NOT quantified in IR units. A sixth cell holding the block constant would bracket it; no such cell is in the pre-registration, so it is future work.
